

I have heard that there is a two step recrystallization process, what is this?

There are several companies who promote a two step recrystallization process. The first step uses the standard recrystallization chemical and then is followed by an application of a second chemical containing waxes which places a higher shine on the surface. Another two step process applies an application of a calcium carbonate fluid and is then followed by an application of a standard recrystallization chemical. Contact the companies who offer these products for further information.

TIP Be sure to test any recrystallization method before attempting to complete the entire job. I have found that some of these two step processes do not work on all marble.
